(57) **ABSTRACT**

A head-protecting airbag device has an airbag deployable downward from a housing area. The airbag includes front and rear window cover portions for covering front and rear windows and a pillar cover portion for covering a middle pillar located between the windows. The pillar cover portion includes in the upper region an inlet port for taking in an inflation gas from one of the window cover portions. The pillar cover portion further includes an upper portion extending in a front and rear direction from the inlet port, and a lower portion which communicates with the upper portion at an end of the upper portion facing away from the inlet port and turns around downward from the upper portion and extends in a front and rear direction beneath the upper portion. The leading end of the lower portion located generally beneath the inlet port is closed.

**HEAD-PROTECTING AIRBAG DEVICE****CROSS REFERENCE TO RELATED APPLICATIONS**

The Present application claims priority from Japanese Patent Application No. 2014-013752 of Kashio, filed on Jan. 28, 2014, the disclosure of which is hereby incorporated into the present application by reference.

**BACKGROUND OF THE INVENTION****1. Field of the Invention**

The present invention relates to a head-protecting airbag device having an airbag that is adapted to be stored at upper peripheries of windows of a vehicle in a vehicle interior for deployment over the windows and includes inflatable portions for covering inboard sides of the windows and a pillar disposed between the windows.

**2. Description of Related Art**

WO 2013/018781 A discloses a head-protecting airbag device having an airbag that covers inboard sides of front and rear windows of a vehicle as well as an inboard side of a middle pillar disposed between the windows upon deployment. In this airbag, a pillar cover portion for covering the middle pillar takes in an inflation gas from a front window cover portion for covering a window located in front of the middle pillar.

However, the pillar cover portion takes in an inflation gas also from a rear window covering portion for covering a window located at the rear of the middle pillar. Further, the pillar cover portion also includes an outlet port which forwards an inflation gas to an inflatable portion located in front of the front window covering portion.

With this configuration, with an inflation gas from the front window covering portion as well as from the rear window covering portion, the pillar cover portion may inflate almost simultaneously with the front window cover portion. In such an instance, if an inflated portion contacts a seatback of a seat located at an inboard side of the middle pillar, the pillar cover portion may fail to deploy to the lower edge but complete inflation at a side of the seat, which may further cause an incomplete deployment of the front window cover portion and rear window cover portion.

JP2009-227161 A also describes an airbag provided with a pillar cover portion. The pillar cover portion serves as a secondary inflatable portion which helps prevent an abrupt boost of an internal pressure in a front window cover portion as a primary inflatable portion.

Since this pillar cover portion takes in an inflation gas only from the front window cover portion, the pillar cover portion inflates only after the front window cover portion starts to inflate. Accordingly, the airbag easily unfolds to the lower edge in an initial stage of airbag deployment between a middle pillar and a seat located at an inboard side of the middle pillar. However, since the pillar cover portion is formed into a rectangular cell elongated in an up and down direction as viewed from a vehicle interior, if it inflates while unfolding downward and contacts a seatback, the pillar cover portion may fail to deploy to the lower edge but complete inflation at a side of the seat, which may further cause an incomplete deployment of the front window cover portion and rear window cover portion as the above.

**SUMMARY OF THE INVENTION**

An object of the present invention is to provide a head-protecting airbag device which is capable of deploying an

airbag to the lower edge smoothly and adequately although the airbag includes a pillar cover portion deployable at an inboard side of a middle pillar.

The airbag apparatus according to the present invention includes an airbag in a folded-up configuration which is adapted to be stored in a housing area disposed at upper peripheries of a plurality of windows arranged one behind another in a front and rear direction of a vehicle. The airbag is deployable downward at an inboard side of the windows and a middle pillar located between the windows when fed with an inflation gas. The airbag includes a gas admittance region that is inflatable with an inflation gas in such a fashion as to separate an inboard side wall from an outboard side wall. The gas admittance region includes window cover portions for covering the windows, respectively, and a pillar cover portion for covering the middle pillar. The pillar cover portion includes at the upper region an inlet port which is in gas communication with one of the window cover portions located in front of and at the rear of the pillar cover portion for taking in an inflation gas from the window cover portion. The pillar cover portion further includes an upper inflatable portion extending in a front and rear direction from the inlet port and a lower inflatable portion which is in gas communication with the upper inflatable portion at an end of the upper inflatable portion facing away from the inlet port and extends in such a fashion as to turn around downward from the upper inflatable portion and extends in a front and rear direction beneath the upper inflatable portion. The lower inflatable portion includes generally beneath the inlet port a closed leading end. The pillar cover portion inflates and completes inflation with an inflation gas taken in from the inlet port.

With the head-protecting airbag device thus configured, at airbag deployment, the pillar cover portion takes in an inflation gas from one of the adjoining window cover portions via the inlet port and starts to inflate. The inflation gas firstly inflates the upper inflatable portion, and then turns around and inflates the lower inflatable portion. That is, the pillar cover portion does not inflate entirely in an up and down direction but firstly the upper inflatable portion extending in a front and rear direction inflates and then the lower inflatable portion inflates. The upper inflatable portion inflates before the lower inflatable portion starts to inflate. By the time the lower inflatable portion starts to inflate, the adjoining window cover portions have inflated and been unfolded to the lower edges sufficiently, thereby providing an environment for the lower inflatable portion to start to inflate. That is, since the adjoining window cover portions have been unfolded to the lower edges before the lower inflatable portion starts to inflate, the pillar cover portion will be capable of unfolding up to the lower edge. As a consequence, an engagement between the pillar cover portion and a vehicle seat will be prevented, and a smooth deployment of the entire airbag will be secured, and the pillar cover portion will deploy over the middle pillar with the inflated upper inflatable portion and lower inflatable portion.

Since the pillar cover portion is designed to inflate and complete inflation with an inflation gas taken in from the inlet port and a fixed streaming motion of an inflation gas is expected, the pillar cover portion will inflate in order from the upper inflatable portion to the lower inflatable portion in a steady fashion, and an operation described above will be exerted in a steady fashion as well.

Therefore, the head-protecting airbag device of the present invention will be capable of deploying an airbag up to the lower edge smoothly and adequately although it is provided with a pillar cover portion deployable at an inboard side of a middle pillar.

3

The head-protecting airbag device of the present invention may also be configured as follows:

The airbag further includes a non-admissive region that admits no inflation gas and where the inboard side wall and the outboard side wall stay attached together. The non-admissive region includes a peripheral portion which defines an outer peripheral edge of the gas admissive region and a partitioning portion which partitions areas of the gas admissive region. The partitioning portion includes an upper edge partitioning portion which partitions the upper inflatable portion of the pillar cover portion from an inflatable portion located above the upper inflatable portion, and a front edge partitioning portion and a rear edge partitioning portion which are located at front and rear edges of the pillar cover portion and partitions the pillar cover portion from the window cover portions. The pillar cover portion is surrounded by the upper edge partitioning portion, a region of the peripheral portion disposed at a lower edge of the lower inflatable portion, the front edge partitioning portion and the rear edge partitioning portion. The partitioning portion further includes a horizontal partitioning portion which extends in a front and rear direction from a region of either the front edge partitioning portion or the rear edge partitioning portion where the inlet port is provided, and partitions the upper inflatable portion from the lower inflatable portion.

With this configuration, the pillar cover portion uses the peripheral portion disposed at the lower edge of the airbag as the lower edge, and there is no other inflatable portion below the pillar cover portion. Therefore, the pillar cover portion will steadily unfold up to the lower edge and be deployed at an inboard side of the middle pillar before inflating, with the aid of unfolding of the adjoining window cover portions.

In this configuration, it is desired that the upper edge partitioning portion includes at the end facing toward the inlet port a leading-end bulged portion which is widened generally in a round shape for preventing stress concentration upon airbag inflation and protrudes toward the upper inflatable portion, and that the horizontal partitioning portion includes at the end facing away from the inlet port a leading-end bulged portion which is widened generally in a round shape for preventing stress concentration and protrudes toward the upper inflatable portion.

With this configuration, since each of the upper edge partitioning portion and the horizontal partitioning portion surrounding the pillar cover portion has at the leading end the round bulged portion, the pillar cover portion will be prevented from a damage from stress concentration due to increase of an internal pressure upon cushioning an occupant as well as upon completion of inflation.

Moreover, with such leading-end bulged portions, an inflation gas flows into the upper inflatable portion via the inlet port in an upwardly expanding fashion due to the leading-end bulged portion protruding downward, and then the gas flows upward in a vicinity of the leading end of the horizontal partitioning portion due to the leading-end bulged portion protruding upward before heading downward to the lower inflatable portion. The gas then flows downward toward the lower inflatable portion while forming a reverse U shaped current, and then flows toward the leading end of the lower inflatable portion. That is, since an inflation gas makes a detour in an up and down direction in the upper inflatable portion, the lower inflatable portion will start to inflate in a delayed fashion by the detour, and be unfolded further smoothly without contacting a vehicle seat and not cause an incomplete deployment of the airbag.

It is further desired in the head-protecting airbag device of the invention that the pillar cover portion is surrounded

4

entirely, except at the inlet port, by the upper edge partitioning portion, the peripheral portion, the front edge partitioning portion and the rear edge partitioning portion.

With this configuration, the pillar cover portion will take in an inflation gas only from the inlet port, and will be steadily prevented from a fear of contacting a seat which can cause an incomplete deployment, and be unfolded and inflate.

Moreover, it is desired that the inflatable portion located above the upper edge partitioning portion is a gas feed path that provides gas communication between the window cover portions.

With this configuration, the front window cover portion and rear window cover portion located in front of and at the rear of the pillar cover portion will unfold and start to inflate generally at the same time with an inflation gas having flown through the gas feed path, which will help the pillar cover portion to unfold quickly up to the lower edge.

#### BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 is a front elevation of a head-protecting airbag device embodying the present invention as mounted on a vehicle, viewed from an interior of the vehicle;

FIG. 2 is a front elevation of an airbag for use in the airbag device of FIG. 1 as is unfolded;

FIG. 3 is an enlarged view of a pillar cover portion of the airbag of FIG. 2;

FIG. 4 is a sectional view of the airbag of FIG. 2 as inflated, taken along line IV-IV of FIG. 2;

FIG. 5 is a sectional view of the airbag of FIG. 2 as inflated, taken along line V-V of FIG. 2;

FIGS. 6A to 6C are schematic vertical sections of the airbag device of FIG. 1 taken along line VI-VI of FIG. 1, depicting the behavior of the airbag device at deployment;

FIG. 7 is a front elevation of the airbag device of FIG. 1 as has completed operation, viewed from an interior of the vehicle; and

FIG. 8 is a front elevation of a modification of the airbag.

#### DESCRIPTION OF PREFERRED EMBODIMENTS

Preferred embodiments of the present invention are described below with reference to the accompanying drawings. However, the invention is not limited to the embodiments disclosed herein. All modifications within the appended claims and equivalents relative thereto are intended to be encompassed in the scope of the claims.

FIG. 1 illustrates a head-protecting airbag device HP embodying the present invention. The airbag device HP includes an airbag 20, an inflator 16 for feeding an inflation gas to the airbag 20, an airbag cover 11, mounting brackets 13, a mounting bracket 17, and bolts 14 and 18. The airbag 20 is stored in a folded-up configuration in a housing area SP disposed at upper peripheries WU of windows (side windows) W1 and W2 of a vehicle V, which windows being disposed one behind the other at a side of a front seat and a rear seat inside a vehicle V. That is, the airbag 20 is stored extendedly in a lower peripheral region of a front pillar FP to a region above a rear pillar RP, via a region above a middle pillar CP.

As shown in FIG. 1, the inflator 16 is formed into a generally cylindrical contour and is inserted into an inlet port 24 of the airbag 20 from which an inflation gas is fed and thus joined with the airbag 20. The inflator 16 is secured to an inner panel 2 at a roof side rail RR located in a vicinity of an upper region of the middle pillar CP, with a mounting bracket 17

5

holding the inflator 16 and mounting bolts 18 for securing the bracket 17 to the inner panel 2. The inflator 16 is covered with a lower rim 5a of a roof head liner 5. The inner panel 2 belongs to a vehicle body structure 1 of the vehicle V.

The inflator 16 is under control of a predetermined control device for detecting a side impact or a rollover of the vehicle V. An output of the inflator 16 corresponds to a volume of the airbag 20, and is so determined that a later-described protection region 26 can maintain a predetermined internal pressure during a side impact and a rollover.

The mounting brackets 13 secure later-described mounting portions 54 of the airbag 20 to the inner panel 2 by mounting bolts 14. Each of the bolts 14 is fastened into a screw hole on the inner panel 2 provided with a nut or the like.

As shown in FIG. 1, the airbag cover 11 is composed of a lower rim 4a of a front pillar garnish 4 arranged on the front pillar FP and the lower rim 5a of the roof head liner 5 arranged on the roof side rail RR, and covers an inboard side of the airbag 20 stored in the housing area SP. The housing area SP is formed on the inner panel 2 at the front pillar FP and the roof side rail RR.

The airbag 20 is foldably flexible, and as shown in FIG. 2, has a hollow-weave or one-piece woven construction of polyamide yarn, polyester yarn or the like, except later-described mounting portions 54. As shown in FIGS. 1 and 7, the airbag 20 is inflatable with an inflation gas G from the inflator 16 and when unfolded and inflated covers inboard sides of the windows W1 and W2, the middle pillar CP and the rear pillar RP. Moreover, the airbag 20 is configured such that its lower edge 20b is supported, at full deployment, by a part of the vehicle body structure (by a door trim, in the illustrated embodiment) DT at the belt line BL, which belt line BL extends along lower edges of the windows W1 and W2 at an inboard side of the vehicle.

Referring to FIGS. 2, 4 and 5, the airbag 20 includes a gas admmissive region 22 inflatable with an inflation gas G by separating an inboard side wall 22a from an outboard side wall 22b, and a non-admmissive region 50 that admits no inflation gas G, in which non-admmissive region 50 the inboard side wall 22a and outboard side wall 22b are attached together.

The gas admmissive region 22 includes window cover portions, i.e., a front window cover portion 27 and a rear window cover portion 35, which cover inboard sides of the windows W1 and W2, respectively, a pillar cover portion 40 for covering an inboard side of the middle pillar CP, a gas feed path 33 which is located above the pillar cover portion 40 and provides gas communication between the front window cover portion 27 and rear window cover portion 35, and a tubular inlet port 24 to be connected to the inflator 16. The inlet port 24 protrudes upward from the center in a front and rear direction of the upper edge 20a of the airbag 20. The gas feed path 33 is in gas communication with the lower end of the inlet port 24 and extends forward and backward. The gas feed path 33 is tubular in shape extending in a front and rear direction along the upper edge 20a of the airbag 20. A trifurcate, heat-resistant inner tube 73 is disposed inside the inlet port 24 for delivering an inflation gas G forward and backward at the location of the gas feed path 33. An inflatable protection region 26 for cushioning an occupant M is composed of a region of the gas admmissive region 22 except the inlet port 24, i.e., composed of the front window cover portion 27, rear window cover portion 35, pillar cover portion 40 and gas feed path 33.

The front window cover portion 27 includes a main inflatable portion 28 as a primary inflatable portion and a sub inflatable portion 29 as a secondary inflatable portion, and is deployable over the front window W1 in front of the middle

6

pillar CP. The main inflatable portion 28 is in gas communication with the front end 33a of the gas feed path 33 so as to be inflatable prior to the sub inflatable portion 29 for protecting a head H of an occupant M seated in a front seat in the event of a side impact, thus located at an upper reach of an inflation gas G than the sub inflatable portion 29 and at the rear of the sub inflatable portion 29. The sub inflatable portion 29 is inflatable in front of the main inflatable portion 28 for addressing a rollover of a vehicle V. The sub inflatable portion 29 has at the rear upper end an inlet port 29a from which to take in an inflation gas from the main inflatable portion 28.

The rear window cover portion 35 includes a main inflatable portion 36 as a primary inflatable portion and a sub inflatable portion 37 as a secondary inflatable portion, and is deployable over the rear window W2 at the rear of the middle pillar CP. The main inflatable portion 36 is in gas communication with the rear end 33b of the gas feed path 33 so as to be inflatable prior to the sub inflatable portion 37 for protecting a head H of an occupant M seated in a rear seat in the event of a side impact, thus located at an upper reach of an inflation gas G than the sub inflatable portion 37 and at the rear of and above the sub inflatable portion 37. The sub inflatable portion 37 is inflatable in front of and beneath the main inflatable portion 36 for addressing a rollover of a vehicle V. The sub inflatable portion 37 has at the upper region in the rear region an inlet port 37a from which to take in an inflation gas from the main inflatable portion 36.

As shown in FIGS. 2 to 5, the pillar cover portion 40 includes an inlet port 41 at the upper region in the front periphery so as to take in an inflation gas G from the main inflatable portion 28 of the front window cover portion 27. The pillar cover portion 40 further includes an upper inflatable portion 42 and a lower inflatable portion 43 which is inflatable beneath the upper inflatable portion 42. The upper inflatable portion 42 extends from the inlet port 41 rearward (i.e., in a front and rear direction) in a rod shape, and has a communication portion 44 located away from the inlet port 41, which communication portion 44 provides gas communication between the upper inflatable portion 42 and lower inflatable portion 43. The lower inflatable portion 43 extends in such a manner as to turn around downward at the communication portion 44 from the upper inflatable portion 42 and extends forward (i.e., in a front and rear direction) beneath the upper inflatable portion 42 in a rod shape. The front end 43b of the lower inflatable portion 43 is closed generally beneath the inlet port 41 of the upper inflatable portion 42.

The non-admmissive region 50 includes a peripheral portion 52 disposed around the gas admmissive region 22, various types of partitioning portions 55, 56, 60, 63, 65 and 67 for partitioning inflatable portions of the airbag 20, thickness regulating portions 70 and 71 for regulating a thickness of the airbag 20 upon inflation and mounting portions 54 arranged in an upper end region 52a of the peripheral portion 52.

The mounting portions 54 are formed in plurality in such a manner as to protrude upward from the upper end region 52a of the peripheral portion 52 at the upper edge 20a of the airbag 20. The airbag 20 of the illustrated embodiment includes seven such mounting portions 54. Each of the mounting portions 54 is provided with an aperture 54a for receiving a mounting bolt 14. Each of the mounting portions 54 is fabricated of a woven fabric of polyamide or the like and is sewn to the upper end region 52a of the peripheral portion 52 of hollow-weave. As described above, each of the mounting portions 54 is coupled with the mounting bracket 13 and secured to the inner panel 2 by the mounting bolt 14 inserted through the aperture 54a and screwed into a screw hole of the inner panel 2. A mounting portion 54F located at the foremost

position is secured to a vicinity of a generally in the middle in an up and down direction of the front pillar FP such that a strong tension force is exerted at airbag deployment at a lower edge **20b** of the airbag **20**, more specifically on a line connecting the mounting portion **54F** and a rearmost mounting portion **54** (**54B**) away from the front pillar FP, and the airbag **20** can securely arrest an occupant M inside the vehicle (FIG. 7).

The thickness regulating portion **70** is located at the rear of the inlet port **29a** of the sub inflatable portion **29** in the main inflatable portion **28** of the front window cover portion **27**. The thickness regulating portion **71** is located above the inlet port **37a** of the sub inflatable portion **37** in the main inflatable portion **36** of the rear window cover portion **35**.

Each of various partitioning portions is linear. The partitioning portions include a front cover partitioning portion **55** which partitions the front window cover portion **27** into the main inflatable portion **28** and sub inflatable portion **29**, a rear cover partitioning portion **56** which partitions the rear window cover portion **35** into the main inflatable portion **36** and sub inflatable portion **37** and those partitioning portions which are arranged around and inside the pillar cover portion **40**, i.e., an upper edge partitioning portion **60**, a front edge partitioning portion **63**, a rear edge partitioning portion **65**, and a horizontal partitioning portion **67**. The front cover partitioning portion **55** extends upward from the lower end region **52b** of the peripheral portion **52** to the inlet port **29a** of the sub inflatable portion **29**. The rear cover partitioning portion **56** includes a front section **57** located in front of the inlet port **37a** of the sub inflatable portion **37** and a rear section **58** located at the rear of the inlet port **37a**. The rear section **58** extends forward from a rear end region **52c** of the peripheral portion **52** and the front section **57** extends rearward from a later-described upper edge partitioning portion **60**.

The upper edge partitioning portion **60** extends in a front and rear direction and partitions the upper inflatable portion **42** of the pillar cover portion **40** from the gas feed path **33** located above the upper inflatable portion **42**. The gas feed path **33** is partitioned at the lower edge from the pillar cover portion **40** and sub inflatable portion **37** by the upper edge partitioning portion **60** and the front section **57** of the rear cover partitioning portion **56**.

The front edge partitioning portion **63** partitions the main inflatable portion **28** of the front window cover portion **27** from the pillar cover portion **40** or lower inflatable portion **43** at the front edge of the lower inflatable portion **43**, and extends upward from the lower end region **52b** of the peripheral portion **52** to the inlet port **41**. The rear edge partitioning portion **65** partitions the sub inflatable portion **37** of the rear window cover portion **35** from the pillar cover portion **40** at the rear edge of the pillar cover portion **40**, and extends upward from the lower end region **52b** of the peripheral portion **52** and continues to an intersection of the upper edge partitioning portion **60** and the front section **57** of the rear cover partitioning portion **56**.

A boundary of the lower edge **40a** of the pillar cover portion **40** is comprised of the lower end region **52b** of the peripheral portion **52**.

The horizontal partitioning portion **63** extends rearward (i.e., in a front and rear direction) from an upper end of the front edge partitioning portion **63** where the inlet port **41** is provided in a linear fashion in such a manner as to go away from the front window cover portion **27**, thus partitions the upper inflatable portion **42** from the lower inflatable portion **43**.

Each of the partitioning portions **55**, **56**, **60** and **67** has at the leading end a widened portion for preventing stress concentration upon airbag inflation. The widened portion of the upper edge partitioning portion **60** formed toward the inlet port **41** constitutes a leading-end bulged portion **61** which is generally round in shape and protrudes downward toward the upper inflatable portion **42**. The widened portion of the horizontal partitioning portion **67** formed away from the inlet port **41** constitutes a leading-end bulged portion **68** which is generally round in shape and protrudes upward toward the upper inflatable portion **42**.

The pillar cover portion **40** of the illustrated embodiment is surrounded entirely, except at the inlet port **40**, by the upper edge partitioning portion **60**, the lower end region **52b** of the peripheral portion **52**, the front edge partitioning portion **63** and the rear edge partitioning portion **65**.

In the illustrated embodiment, the inlet port **41** is so designed as to be located, upon deployment of the airbag **20** after the airbag device HP is mounted on a vehicle V, in a vicinity of a rim (front rim) CPf of the middle pillar CP facing toward the front window W1, as shown in FIG. 7, and the leading end **43b** of the lower inflatable portion **43** is slightly forward toward the front window W1 relative to the inlet port **41**.

In this specific embodiment, moreover, the leading-end bulged portion **68** of the horizontal partitioning portion **67** is located at an intermediate region in an up and down direction of the pillar cover portion **40**, and at an intermediate region in a front and rear direction of the pillar cover portion **40**, more specifically at an intermediate region in a front and rear direction of a general region **62** excepting the leading-end bulged portion **61** of the upper edge partitioning portion **60**.

An opening width O1 of a general region **42a** of the upper inflatable portion **42** except a vicinity of the leading-end bulged portion **61**, an opening width O2 of the communication portion **44** and an opening width O3 of a general region **43a** of the lower inflatable portion **43** are generally identical. More specifically, the opening width O3 of the general region **43a** of the lower inflatable portion **43** is slightly smaller than the opening widths O1 and O2 of the general region **42a** and communication portion **44**.

Further, the lower edge **27a** of the main inflatable portion **28** in the front window cover portion **27** and the lower edge **35a** of the main inflatable portion **36** in the rear window cover portion **35** are arranged at the same level as the lower edge **43c** of the lower inflatable portion **43**, i.e., as the lower edge **40a** of the pillar cover portion **40**.

The inlet port **41** of the pillar cover portion **40** is located immediately beneath the front end **33a** of the gas feed path **33** which is continuous with the inlet port **24** of the airbag **20** to be jointed with the inflator **16**, in other words, immediately beneath the front end **33a** of the gas feed path **33** where an inflation gas G having flown into the airbag **20** has a high pressure. Accordingly, the inlet port **41** will be hardly closed and the pillar cover portion **40** will be fed with an inflation gas steadily.

Mounting of the head-protecting airbag device HP on a vehicle V is now described. Firstly, the airbag **20** is folded up in such a fashion as to bring the lower edge **20b** close to the upper edge **20a**. In the illustrated embodiment, specifically, a lower region of the airbag **20** is rolled on an outboard side toward the upper edge **20a** from the lower edge **20b**, while an area in a vicinity of the gas feed path **33** is folded in a bellows-fashion.

When the airbag **20** is folded up, a breakable wrapping member (not shown) is wound around the airbag **20** for keeping a folded-up configuration. Subsequently, the inflator **16**

with the mounting bracket 17 mounted thereon is connected with the inlet port 24 of the airbag 20, and the mounting brackets 13 are attached to the mounting portions 54 of the airbag 20, thereby forming an airbag module. Thereafter, the mounting portions 54 with the mounting brackets 13 are located at and fastened to the housing area SP on the inner panel 2 of the vehicle body structure 1 by inserting the mounting bolts 14 into the mounting holes 54a and screw holes on the inner panel 2. Further, the inflator 16 is secured to the inner panel 2 by fixing the mounting bracket 17 with the bolts 18, thus the airbag module is mounted on the vehicle body structure 1.

Then the inflator 16 is connected with a not-shown lead wire extending from a suitable control for actuating the inflator. If then the front pillar garnish 4, the roof head liner 5, a middle pillar garnish 7 and a rear pillar garnish 8 are attached to the vehicle body structure 1, the head-protecting airbag device HP is mounted on the vehicle V.

When the head-protecting airbag device HP mounted on the vehicle V is actuated upon a side impact crash or a rollover, the inflator 16 is actuated and discharges an inflation gas G and the gas G flows as indicated by double-dotted lines in FIG. 2, and inflates the protection region 26 of the gas admissible region 22. The airbag 20 then pushes and opens the airbag cover 11 and deploys downward from the upper peripheries WU of windows W1, W2 at an inboard side I of the windows W1, W2 and the middle pillar CP.

At airbag deployment, at an inboard side I of the middle pillar CP, the pillar cover portion 40 takes in an inflation gas G from the main inflatable portion 28 of the front window cover portion 27 via the inlet port 41 and starts to inflate, as shown in FIGS. 3 and 6A to 6C. The inflation gas G firstly inflates the upper inflatable portion 42, and then turns around and inflates the lower inflatable portion 43. That is, the pillar cover portion 40 does not inflate entirely in an up and down direction but firstly the upper inflatable portion 42 extending in a front and rear direction inflates and then the lower inflatable portion 43 inflates. The upper inflatable portion 42 inflates before the lower inflatable portion 43 starts to inflate. By the time the lower inflatable portion 43 starts to inflate, the main inflatable portions 28 and 36 of the front and rear window cover portions 27 and 35 have inflated and the lower edges 27a and 35a of the window cover portions 27 and 35 have been also unfolded sufficiently, thereby providing an environment for the lower inflatable portion 43 to start to inflate. That is, since the front and rear window cover portions 27 and 35 have been unfolded to the lower edges 27a and 35a before the lower inflatable portion 43 starts to inflate, the pillar cover portion 40 will be capable of unfolding up to the lower edge 40a in such a fashion as to be pulled by the unfolding of the window cover portions 27 and 35. As a consequence, an engagement between the pillar cover portion 40 and a seatback SB of a vehicle seat S will be prevented, and a smooth deployment of the entire airbag 20 will be secured, and the pillar cover portion 40 will deploy over the middle pillar CP with the inflated upper inflatable portion 42 and lower inflatable portion 43.

Since the pillar cover portion 40 is designed to inflate and complete inflation with an inflation gas G taken in from the inlet port 41, and a fixed streaming motion of an inflation gas G is expected, the pillar cover portion 40 will inflate in order from the upper inflatable portion 42 to the lower inflatable portion 43 in a steady fashion, and an operation described above will be exerted in a steady fashion as well.

Therefore, the head-protecting airbag device HP of the embodiment will be capable of deploying the airbag 20 up to the lower edge 20b smoothly and adequately although it is

provided with the pillar cover portion 40 deployable at an inboard side of the middle pillar CP.

In the foregoing embodiment, the non-admissible region 50 of the airbag 20 includes the peripheral portion 52 which defines an outer peripheral edge of the gas admissible region 22 and the partitioning portions 55, 56, 60, 63, 65 and 67 which partition areas of the gas admissible region 22. The pillar cover portion 40 is surrounded by the upper edge partitioning portion 60 which partitions the upper inflatable portion 42 from an inflatable portion 33 located above the upper inflatable portion 42, the lower end region 52b of the peripheral portion 52 disposed at the lower edge 43c of the lower inflatable portion 43, the front edge partitioning portion 63 and the rear edge partitioning portion 65 which are located at front and rear edges of the pillar cover portion 40 and partitions the pillar cover portion 40 from the front window cover portion 27 and rear window cover portion 35. Further, the upper inflatable portion 42 and lower inflatable portion 43 of the pillar cover portion 40 are partitioned by the horizontal partitioning portion 67 which extends rearward (in a front and rear direction) from the front edge partitioning portion 63 (from either the front edge partitioning portion 63 or the rear edge partitioning portion 65) where the inlet port 41 is provided.

With this configuration, the pillar cover portion 40 uses the peripheral portion 52 disposed at the lower edge 20b of the airbag 20 as the lower edge 40a, and there is no other inflatable portion below the pillar cover portion 40. Therefore, the pillar cover portion 40 will steadily unfold up to the lower edge 40a and be deployed at an inboard side I of the middle pillar CP before inflating, with the aid of unfolding of the front window cover portion 27 and rear window cover portion 35.

Further, the upper edge partitioning portion 60 includes at the end facing toward the inlet port 41 the leading-end bulged portion 61 which is widened generally in a round shape for preventing stress concentration upon airbag inflation and protrudes toward the upper inflatable portion 42, while the horizontal partitioning portion 67 includes at the end facing away from the inlet port 41 the leading-end bulged portion 68 which is widened generally in a round shape for preventing stress concentration and protrudes toward the upper inflatable portion 42.

Since each of the upper edge partitioning portion 60 and the horizontal partitioning portion 67 surrounding the pillar cover portion 40 has at the leading end the round bulged portion 61/68, the pillar cover portion 40 will be prevented from a damage from stress concentration due to increase of an internal pressure upon cushioning an occupant M as well as upon completion of inflation.

Moreover, with the leading-end bulged portions 61 and 68, as shown in FIG. 3, an inflation gas G flows into the upper inflatable portion 42 via the inlet port 41 in an upwardly expanding fashion due to the leading-end bulged portion 61 bulging downward, and then the gas G flows upward in a vicinity of the leading end of the horizontal partitioning portion 67 due to the leading-end bulged portion 68 protruding upward before heading downward to the lower inflatable portion 43. The gas G then flows downward toward the lower inflatable portion 43 while forming a reverse U shaped current, and then flows toward the leading end 43b of the lower inflatable portion 43. That is, since the inflation gas G makes a detour in an up and down direction in the upper inflatable portion 42, the lower inflatable portion 43 will start to inflate in a delayed fashion by the detour, and be unfolded further smoothly without contacting a seatback SB of a seat S and not cause an incomplete deployment of the airbag 20.

## 11

The pillar cover portion **40** of the foregoing embodiment is surrounded entirely, except at the inlet port **41**, by the upper edge partitioning portion **60**, the lower end region **52b** of the peripheral portion **52**, the front edge partitioning portion **63** and the rear edge partitioning portion **65**.

With this configuration, the pillar cover portion **40** will take in an inflation gas **G** only from the inlet port **41**, and will be steadily prevented from a fear of contacting a seatback **SB** of a seat **S** which may cause an incomplete deployment, and be unfolded

It will be conceivable to form a small opening in the lower inflatable portion **43** or in the upper inflatable portion **42** for communication with the front window cover portion **27** or rear window cover portion **35** as long as the pillar cover portion **40** is capable of unfolding in a steady fashion and start to inflate with an inflation gas from the inlet port **41**.

In the illustrated embodiment, the inflatable portion located above the upper edge partitioning portion **60** is the gas feed path **33** that provides gas communication between the front window cover portion **27** and rear window cover portion **35**.

With this configuration, the front window cover portion **27** and rear window cover portion **35** located in front of and at the rear of the pillar cover portion **40** will unfold and start to inflate generally at the same time with an inflation gas **G** having flown through the gas feed path **33**, which will help the pillar cover portion **40** to unfold quickly up to the lower edge **40a**.

Although the inlet port **41** of the pillar cover portion **40** is located at the front region of the pillar cover portion **40** in the foregoing embodiment, the inlet port may be located at a rear region of the pillar cover portion, as in an airbag **20A** depicted in FIG. **8**. In the airbag **20A**, a pillar cover portion **40A** has an inlet port **41A** between a rear end of an upper edge partitioning portion **60A** and an upper end of a rear edge partitioning portion **65A** for taking in an inflation gas **G** from the rear window cover portion **35**.

The pillar cover portion **40** in the foregoing embodiment is provided to deploy over an inboard side of the middle pillar (center pillar, B-pillar) **CP** located between a front seat and a rear seat of a vehicle **V**. In addition, a pillar cover portion according to the present application may be so provided as to cover other pillar together with window cover portions located in front of and at the rear of the pillar cover portion. By way of example, in a head-protecting airbag device for a vehicle with three-row seating, a pillar cover portion according to the invention may be provided to cover an inboard side of a middle pillar (C-pillar) located between a second-row seating and a third-row seating. It will also be conceivable to form a pillar cover portion for covering a middle pillar (B-pillar) located between a first row seating and the second-row seating.

Further, although the airbag **20** in the foregoing embodiment has been described as has a hollow-weave construction, an airbag according to the invention may be formed by sewing together an inboard side wall **22a** and an outboard side wall **22b** at the peripheral portion **52**, the partitioning portions **55**, **56**, **60**, **63**, **65**, **67** or at the thickness regulating portions **70** and **71**.

What is claimed is:

1. A head-protecting airbag device having an airbag in a folded-up configuration that is adapted to be stored in a housing area disposed at upper peripheries of a plurality of windows arranged one behind another in a front and rear direction of a vehicle, the airbag being deployable downward at an

## 12

inboard side of the windows and a middle pillar located between the windows when fed with an inflation gas, the airbag comprising:

a gas admittive region that is inflatable with an inflation gas in such a fashion as to separate an inboard side wall from an outboard side wall and comprises window cover portions for covering the windows respectively and a pillar cover portion for covering the middle pillar, the pillar cover portion comprising:

an inlet port that is located in an upper region of the pillar cover portion and is in gas communication with one of the window cover portions located in front of and at the rear of the pillar cover portion for taking in an inflation gas from the window cover portion such that the pillar cover portion inflates and completes inflation with an inflation gas taken in from the inlet port, wherein the pillar cover portion includes only one inlet port;

an upper inflatable portion that extends in a front and rear direction from the inlet port; and

a lower inflatable portion that is in gas communication with the upper inflatable portion at an end of the upper inflatable portion facing away from the inlet port and extends in such a fashion as to turn around downward from the upper inflatable portion and extends in a front and rear direction beneath the upper inflatable portion, the lower inflatable portion comprising generally beneath the inlet port a closed leading end.

2. The head-protecting airbag device according to claim 1, wherein:

the airbag further comprises a non-admittive region that admits no inflation gas and where the inboard side wall and the outboard side wall stay attached together, the non-admittive region comprising:

a peripheral portion defining an outer peripheral edge of the gas admittive region;

an upper edge partitioning portion that partitions the upper inflatable portion of the pillar cover portion from an inflatable portion located above the upper inflatable portion;

a front edge partitioning portion and a rear edge partitioning portion that are located at front and rear edges of the pillar cover portion and partitions the pillar cover portion from the window cover portions; and

a horizontal partitioning portion extending in a front and rear direction from a region of either the front edge partitioning portion or the rear edge partitioning portion where the inlet port is provided, the horizontal partitioning portion partitioning the upper inflatable portion from the lower inflatable portion; and

the pillar cover portion is surrounded by the upper edge partitioning portion, a region of the peripheral portion disposed at a lower edge of the lower inflatable portion, the front edge partitioning portion and the rear edge partitioning portion.

3. The head-protecting airbag device according to claim 2, wherein:

the upper edge partitioning portion includes at an end thereof facing toward the inlet port a leading-end bulged portion which is widened generally in a round shape for preventing stress concentration upon airbag inflation and protrudes toward the upper inflatable portion; and

the horizontal partitioning portion includes at an end thereof facing away from the inlet port a leading-end bulged portion which is widened generally in a round shape for preventing stress concentration and protrudes toward the upper inflatable portion.

**13**

4. The head-protecting airbag device according to claim 2, wherein the pillar cover portion is surrounded entirely, except at the inlet port, by the upper edge partitioning portion, the peripheral portion, the front edge partitioning portion and the rear edge partitioning portion.

5

5. The head-protecting airbag device according to claim 2, wherein the inflatable portion located above the upper edge partitioning portion is a gas feed path that provides gas communication between the window cover portions.
